In analytic geometry, an asymptote (/ ˈæːmptə ˈtɔːl /) of a curve is a line such that the distance between the curve and the line approaches zero as one or both of the x or y coordinates tends to infinity.

In mathematics and physics, homogenization is a method of studying partial differential equations with rapidly oscillating coefficients, such as  $\hat{\epsilon}^\epsilon \dots ((\hat{\epsilon}^\epsilon) \hat{\epsilon}^\epsilon) =$  where  $\epsilon$  is a very small parameter and  $(\hat{\epsilon}^\epsilon)$  is a 1-periodic coefficient:  $(\hat{\epsilon}^\epsilon + \hat{\epsilon}^\epsilon) = (\hat{\epsilon}^\epsilon)$ ,  $\epsilon \in \mathbb{R}$ . It turns out that the study of these equations is also of great importance in physics and engineering, since equations of this type govern the physics of inhomogeneous or heterogeneous materials.

Box and Cox (1964) developed the transformation. Estimation of any Box-Cox parameters is by maximum likelihood. Box and Cox (1964) offered an example in which the data had the form of survival times but the underlying biological structure was of hazard rates, and the transformation identified this.
